# 13.0 Optical Instruments

FlexBooks® 2.0 > Waves FlexBook 2.0 > Optical Instruments

Last Modified: May 29, 2019

---

This colorful burst of “spaghetti” is really a bundle of optical fibers. These are hair-thin threads of glass that transmit laser light that has been encoded with messages. Optical fibers are a crucial component of modern communications. The use of light in devices such as these is possible because of optics.

## Optics and Optical Instruments

**Optics** is the study of visible light and the ways it can be used to extend human **vision** and do other tasks. Knowledge of light was needed for the invention of optical instruments such as microscopes, **telescopes**, and cameras, in addition to optical fibers. These instruments use **mirrors** and **lenses** to reflect and refract light and form images.

**Q:** What is an image?

**A:** An image is a copy of an object created by the **reflection** or **refraction** of visible light.

## Light Microscope

A light **microscope** is an instrument that uses **lenses** to make enlarged images of objects that are too small for the unaided eye to see. A common type of light microscope is a **compound** microscope, like the one shown in the **Figure below**. A **compound microscope**

has at least two convex **lenses**: one or more objective lenses and one or more eyepiece lenses. The objective lenses are close to the object being viewed. They form an enlarged image of the object inside the microscope. The eyepiece lenses are close to the viewer's **eyes**. They form an enlarged image of the first image. The magnifications of all the lenses are multiplied together to yield the overall magnification of the microscope. Some light microscopes can magnify objects more than 1000 times!

**Q:** How has the microscope advanced scientific knowledge?

**A:** The microscope has revealed secrets of the natural world like no other single invention. The microscope let scientists see entire new worlds, leading to many discoveries—especially in biology and medicine—that could not have been made without it. Some examples include the discovery of **cells** and the identification of **bacteria** and other single-celled organisms. With the **development** of more powerful microscopes, viruses were discovered and even atoms finally became visible. These discoveries changed our ideas about the **human body** and the nature of life itself.

Launch the PLIX Interactive below to further explore the parts of a microscope:

<https://flexbooks.ck12.org/assessment/tools/geometry-tool/fullscreen.html?qID=5457ee118e0e0867607a339d>

## Telescope

Like microscopes, **telescopes** use convex lenses to make enlarged images. However, telescopes make enlarged images of objects—such as distant stars—that only appear tiny because they are very far away. There are two basic types of telescopes: reflecting telescopes and refracting telescopes. The two types are compared in the **Figure below**. They differ in how they collect light, but both use convex lenses to form enlarged images.

<https://flexbooks.ck12.org/flx/render/embeddedobject/193531>

## Reflecting Telescope

A reflecting telescope uses a concave mirror to collect and focus light. The light then strikes a smaller plane mirror, which reflects the light into the eyepiece at the side of the microscope. (The eyepiece is on the side so it doesn't block incoming light.) A convex lens in the eyepiece enlarges the image.

## Refracting Telescope

A refracting telescope uses a convex lens to collect and focus light. It uses another convex lens in the eyepiece to enlarge the image made by the first convex lens.

Play around with a Cassegrain Telescope in the simulation below and see if you can adjust the sliders to create a clear view of **Jupiter** in the eyepiece:

## Camera

A camera is an optical instrument that forms and records an image of an object. The image may be recorded on film or it may be detected by an electronic sensor that stores the image digitally. Regardless of how the image is recorded, all cameras form images in the same basic way, as shown in the **Figure below**.

- Light passes through the lens at the front of the camera and enters the camera through an opening called the aperture.

- As light passes through the lens, it forms a reduced real image. The image focuses on film (or a sensor) at the back of the camera. The lens may be moved back and forth to bring the image into focus.
- The shutter controls the amount of light that actually strikes the film (or sensor). It stays open longer in dim light to let more light in.

## Lasers

Did you ever see a cat chase after a laser light, like the one in **Figure below**? A **laser** is a device that produces a very focused beam of visible light of just one **wavelength** and **color**. Waves of laser light are synchronized so the crests and troughs of the waves line up. The diagram in **Figure below** shows why a beam of laser light is so focused compared with ordinary light from a flashlight.

The following **Figure below** provides a closer look at the tube where laser light is created. Electrons in a material such as a ruby crystal are stimulated to radiate photons of light of one **wavelength**. At each end of the tube is a concave mirror. The photons of light reflect back

and forth in the tube off these **mirrors**. This focuses the light. The mirror at one end of the tube is partly transparent. A constant stream of photons passes through the transparent part, forming the laser beam.

<https://flexbooks.ck12.org/flx/render/embeddedobject/5054>

## Optical Fibers

Besides entertaining a cat, laser light has many other uses. One use is carrying **communication** signals in optical fibers. Sounds or pictures are encoded in pulses of laser light, which are then sent through an optical fiber. All of the light reflects off the inside of the fiber, so none of it escapes. As a result, the signal remains strong even over long distances. More than one signal can travel through an optical fiber at the same time, as you can see in the **Figure below**. Optical fibers are used to carry telephone, cable TV, and Internet signals.

---

*The optical fiber in the diagram is much larger than a real optical fiber, which is only about as wide as a human hair.*

---

**Q:** When **lasers** were invented in 1960, they were called "a **solution** looking for a problem." Since then, they have been put to thousands of different uses. Can you name other ways

that lasers are used?

**A:** The first widespread use of lasers was the supermarket barcode scanner, introduced in 1974. The compact disc (CD) player was the first laser-equipped device commonly used by consumers, starting in 1982. The CD player was quickly followed by the laser printer. Some other uses of lasers include bloodless surgery, cutting and welding of **metals**, guiding missiles, thermometers, laser light shows, and acne treatments.

## Summary

- Optics is the study of visible light and the ways it can be used to extend human **vision** and do other tasks. Optical instruments are based on optics. They use **mirrors** and lenses to reflect and refract light and form images.
- The light microscope and telescope use convex lenses and mirrors to make enlarged images of very tiny or distant objects. A camera uses a convex lens to make a reduced image of an object.
- A laser is a device that produces a very focused beam of visible light of just one **wavelength** and **color**. Pulses of laser light carry **communication** signals through optical fibers.

## Review

1. Define optics.
2. Explain how a **compound** microscope uses convex lenses to make an enlarged image of a tiny object.
3. Compare and contrast reflecting and refracting **telescopes**.
4. Write a paragraph explaining how a camera works. Assume you are explaining it to a much younger student. Draw a sketch as a visual aid.
5. Explain how **reflection** is involved in the production of laser light.
6. How are optical fibers used?
